AI Hackathon with Nebius & NVIDIA

Challenge: a dark factory for bug fixing

Build the confidence layer that lets a repo fix its own small bugs and ship them to production with nobody approving the change by hand, and have the team actually sleep at night.

The problem. Pointing a coding agent at a bug and getting a plausible fix is basically a solved thing. What stops it being autonomous is that nobody will merge and deploy that fix without reading it first. So a human stays in the loop, the loop becomes the bottleneck, and the autonomy quietly disappears. That makes this a trust problem, not a capability one.

What you build. The goal is a system that earns enough confidence in a fix to deploy it autonomously, with no human approving the change. How you get there is up to you. See "AI Hackathon with Nebius & NVIDIA.pdf" for more details.

Where Token Factory comes in. Nebius Token Factory gives you an OpenAI-compatible API over open models like DeepSeek, Qwen, Llama, and Kimi. You can run the agents live during the event instead of standing up your own GPUs.
